Heterogeneity in the nature of T cells infiltrating laryngeal mucosa. The pathogenesis of organ-specific autoimmune diseases is still poorly understood. Infiltration of autoimmune T cells into target tissues, including the laryngeal mucosa, is considered one of the important mechanisms leading to tissue destruction. To study the T cell infiltrates in laryngeal mucosa, an in-house developed staining system was used. In normal and inflamed laryngeal mucosa of patients with autoimmune disease, CD3+ and CD4+ cell infiltrates were detected in the lamina propria. The distribution of cell infiltrates in normal and inflamed laryngeal mucosa varied widely. The CD8+ cell infiltrate was strikingly heterogeneous both in the number of CD8+ cells per square millimeter of epithelium and in the prevalence of CD8+ cells in intraepithelial lymphocyte (IEL) infiltrate. Both subsets of T lymphocytes, CD3+ and CD8+, constituted the majority of the laryngeal IEL infiltrate. The spatial arrangement of T cells within the laryngeal mucosa differed significantly from that of peripheral blood lymphocytes. Analysis of laryngeal cells using cluster analysis showed that the major cell populations differed not only in the number of cells per millimeter but also in the overall composition of the infiltrate. For example, CD4+ cells were abundant in the epithelium, whereas CD8+ cells were predominantly in the lamina propria. Among the various disease states, severe disease showed more predominant infiltrates of T cells into the lamina propria, whereas a smaller number of cells with the CD8+ phenotype were detectable in the epithelium. Taken together, these data support the notion that laryngeal T cell infiltrates are likely to be important in the pathogenesis of laryngeal autoimmune disease. This subproject is one of many research subprojects utilizing the resources provided by a Center grant funded by NIH/NCRR. The subproject and investigator (PI) may have received primary funding from another NIH source, and thus could be represented in other CRISP entries. The institution listed is for the Center, which is not necessarily the institution for the investigator. The objective of the project was to perform a comparative analysis of the crystallographic structures of a number of other proteins that share a major portion of the active site of the HIV-1 integrase core domain with the prototypical inhibitor [N

1. Field of the Invention This invention pertains to therapeutic devices for use in the reduction of pressure in the sacrum region of the human back, and more particularly pertains to a device for such pressure reduction which is particularly useful when applied to the sacrum when the patient is in a side lying position. 2. Description of the Prior Art In some patients a wide variety of problems may be found in the sacrum region and surrounding adjacent regions of the human spine. The sacrum region is associated with the large pelvic bones and the vertebrae of the human spine. The underlying bones are not well adapted to accommodate the formation of the pelvic structure, and the result is that the pelvic bones and the adjacent vertebrae are under a wide variety of conditions strained or compressed in both a forward and backward direction, and from side to side. This wide variety of compression of the sacrum region and/or the associated vertebrae or pelvic bones is aggravated by such conditions as lumbar spine curvature, scoliosis, or lateral curvature of the spine. These conditions will give rise to a variety of strain patterns and, in some cases, distortion of the pelvis. This wide variety of strain and distortion in the sacrum region is a primary reason that the patient may suffer from a wide variety of conditions which are of functional and cosmetic importance. The conditions of the patient often are aggravated by the presence of the sacrum region in a flattened position due to the presence of such conditions as scoliosis or lateral curvature. In such case, the sacrum region will have a flattened condition which bears down or is "packed" against other structures and, in some cases, may even develop into a vertebral fracture. In some instances, bone changes in the sacrum region are found which result in bone growth in response to the pressure so applied to the sacrum and sacral region. The bone growth has a wide variety of consequences which are not generally to the patient's benefit. For example, the growth of bone in the sacrum region may result in a "fused" or bound sacrum, making the patient's walking and/or sexual function greatly inhibited, if not prevented. Particularly in patients whose lumbar spine is curved, the strain and distortion of the sacrum region is aggravated, as noted above. Such conditions result in an unstable sacrum which is frequently shifted sideways into a side lying position. Those skilled in the art of treating the sacrum region recognize that good
